S1 Additional numerical results
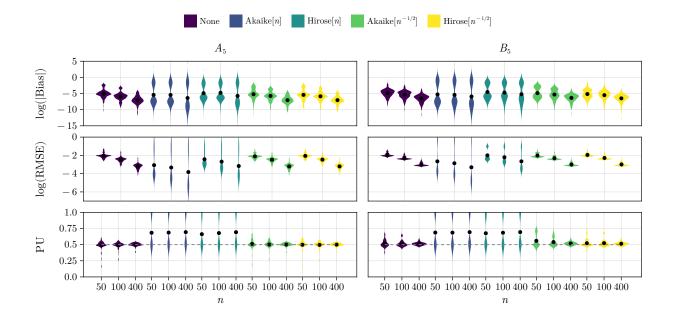

S1.1 Simulation results

Figure S1: Violin plots of estimates of log(|Bias|) (top panel), log(RMSE) (middle panel) and probability of underestimation (bottom panel) for the elements of $\mathbf{\Lambda}\mathbf{\Lambda}^\top$, for each estimator, $n \in \{50, 100, 400\}$, and loading matrix settings A_5 and B_5. The average over all elements for each setting is noted with a dot.

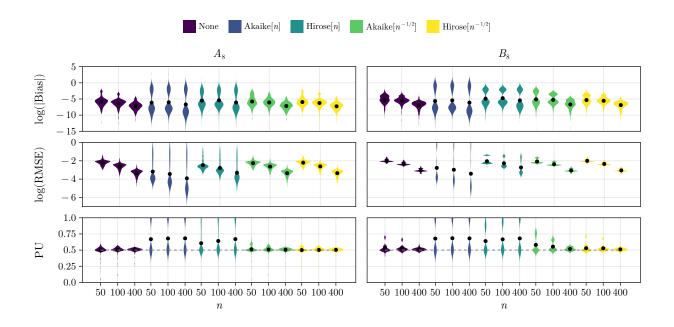

Figure S2: Violin plots of estimates of log(|Bias|) (top panel), log(RMSE) (middle panel) and probability of underestimation (bottom panel) for the elements of $\boldsymbol{\Lambda\Lambda}^\top$, for each estimator, $n \in \{50, 100, 400\}$, and loading matrix settings A_8, and B_8. The average over all elements for each setting is noted with a dot.

S1.2 Data examples

Table S1: Estimates of $\mathbf{\Lambda}$ and $\mathbf{\Psi}$ for the Davis data using ML and MSPL with Akaike$[n^{-1/2}]$ and Hirose$[n^{-1/2}]$ penalties. A value 0.00 indicates a positive estimate that is less than 0.01, and -0.00 indicates a negative estimate that is greater than -0.01.

S2   Proofs

S2.1   Existence

We start by stating an existence master theorem, which we use to establish our existence results for MPL in factor analysis.

Theorem A1 (Existence master theorem). *Let $\mathcal{X} \subseteq \Re^d$, denote by $\mathrm{cl}(\mathcal{X})$ its closure and let $\partial\mathcal{X} \subseteq \mathrm{cl}(\mathcal{X})$ be a set of sequential limit points of $\mathcal{X}$ and denote $\mathrm{int}(\mathcal{X}) = \mathrm{cl}(\mathcal{X}) \setminus \partial\mathcal{X}$.*
Let $h : \mathcal{X} \to \Re$ be a function such that

A1) $h(x)$ *is continuous on* $\mathcal{X}$

A2) $\sup\limits_{x\in\mathcal{X}} h(x) < \infty$

A3) For any sequence $\{x_n\}_{n\in\mathbb{N}}$, $x_n \in \mathcal{X}$ such that either $\lim_{n\to\infty} x_n \in \partial\mathcal{X}$,[1] or $\|x_n\| \to \infty$, $\lim_{n\to\infty} h(x_n) = -\infty$

Then the set of maximisers is nonempty, i.e.

$$\left\{ x^* \in \text{int}(\mathcal{X}) : h(x^*) = \sup_{x\in\mathcal{X}} h(x) \right\} \neq \emptyset.$$

Proof. Towards a contradiction, assume that supremum of h is not attained in $\text{int}(\mathcal{X})$, that is, for all $x \in \text{int}(\mathcal{X})$, $h(x) < H^*$, where $H^* = \sup_{x\in\mathcal{X}} h(x)$. Note that by assumption A2), $H^* \in \Re$.

Construct a sequence $\{x_n\}_{n\in\mathbb{N}}$, $x_n \in \mathcal{X}$ such that $\lim_{n\to\infty} h(x_n) = H^*$. To do this, note that for any $\varepsilon > 0$, one can find a $x \in \mathcal{X}$ for which $H^* - h(x) < \varepsilon$. If this were not the case then, there must exist a $\varepsilon > 0$ such that for all $x \in \mathcal{X}$, $H^* - \varepsilon > h(x)$, contradicting the least upper bound property of H^*. Thus, one can construct $\{x_n\}_{n\in\mathbb{N}}$ by choosing any element of the set $\{x \in \mathcal{X} : H^* - h(x) < 1/n\}$.

Next, note that $\{x_n\}_{n\in\mathbb{N}}$ must be bounded. For this, assume that on the contrary $\|x_n\| \to \infty$ as $n \to \infty$. Then by A3), $h(x_n) \to -\infty$ as $n \to \infty$. But then for every $r \in \Re$ there exists a $N \in \mathbb{N}$ such that for all $n > N$, $h(x_n) < r$. But this stands in contradiction to the construction of $\{x_n\}_{n\in\mathbb{N}}$, for which $\{h(x_n)\}_{n\in\mathbb{N}}$ ought to converge to $H^* \in \Re$.

Then, by the Bolzano-Weierstrass theorem (see for example Rudin 1976, Theorem 3.6 (b)), $\{x_n\}_{n\in\mathbb{N}}$ must contain a convergent subsequence, say $\{x_{n_k}\}_{k\in\mathbb{N}}$, with limit $x^* \in \text{cl}(\mathcal{X})$ and where $\{n_k\}_{k\in\mathbb{N}} \in \mathbb{N} : n_s < n_t$ for $s < t$. Now, by construction of $\text{int}(\mathcal{X}) = \text{cl}(\mathcal{X}) \setminus \partial\mathcal{X}$, one of the the two cases below must hold.

(i) $x^* \in \text{int}(\mathcal{X})$: Then, using that the subsequential limit of a convergent sequence must equal the limit of that sequence (e.g. Rudin 1976, Definition 3.5), it follows that

$$H^* = \lim_{k\to\infty} h(x_{n_k}) = h\left(\lim_{k\to\infty} x_{n_k}\right) = h(x^*),$$

where the second equality follows from continuity of $h(x)$, which holds by A1). But then there exists a $x^* \in \text{int}(\mathcal{X})$ such that $h(x^*) = H^* = \sup_{x\in\mathcal{X}} h(x)$ which was assumed not to be case.

(ii) $x^* \in \partial\mathcal{X}$: Then

$$H^* = h(x^*) = h\left(\lim_{k\to\infty} x_{n_k}\right) = \lim_{k\to\infty} h(x_{n_k}) = -\infty,$$

where the third equality follows since $h(x)$ is continuous on $\mathcal{X}$ (see for example Rudin 1976, Theorems 4.6-4.7) which holds by A1) and the last from the decay condition A3). This stands in contradiction to $H^* \in \Re$.

Since either case leads to a contradiction, the initial assumption must be false. Thus, there must exists a $x^* \in \text{int}(\mathcal{X}) : h(x^*) = H^*$.

□

Next, we state a general existence theorem for factor analysis. This result is more general than the existence Theorem 1 stated in the main text. In particular, it allows optimisation to be conducted in a general parameter space $\Theta \subseteq \Re^d$, to allow for any potential constraints that one wishes to impose on the optimisation problem. Each vector $\boldsymbol{\theta} \in \Theta$ is mapped to a symmetric, positive definite, $p \times p$ matrix through the map $\boldsymbol{\theta} \mapsto s(\boldsymbol{\theta})$.

Theorem A2. *Let $\Theta \subseteq \Re^d$, denote by $\text{cl}(\Theta)$ its closure, $\partial\Theta \subseteq \text{cl}(\Theta)$ a set of sequential limit points of Θ, and denote $\text{int}(\Theta) = \text{cl}(\Theta) \setminus \partial(\Theta)$.*

Let $s : \boldsymbol{\theta} \mapsto s(\boldsymbol{\theta})$ be a mapping from Θ to the space of $p \times p$ positive definite and symmetric matrices and define $\ell^*(\boldsymbol{\theta}; \boldsymbol{S}) = \ell(s(\boldsymbol{\theta}); \boldsymbol{S}) + P^*(\boldsymbol{\theta})$, where $\ell(\boldsymbol{\Sigma}; \boldsymbol{S})$ is the profile log-likelihood of the EFA model in Section 2 and $\boldsymbol{S}$ is full rank.

Assume that:

---

[1] Formally: $\lim_{n\to\infty} \inf_{x\in\partial\mathcal{X}} \|x_n - x\| = 0$.

A4) s and P^* are continuous on $\boldsymbol{\Theta}$

A5) For any sequence $\{\boldsymbol{\theta}_n\}_{n\in\mathbb{N}}$, $\boldsymbol{\theta}_n \in \boldsymbol{\Theta}$, such that $\|\boldsymbol{\theta}_n\| \to \infty$ as $n \to \infty$, either $P^*(\boldsymbol{\theta}) \to -\infty$ or $\|\|s(\boldsymbol{\theta}_n)\|\| \to \infty$

A6) For any sequence $\{\boldsymbol{\theta}_n\}_{n\in\mathbb{N}}$, $\boldsymbol{\theta}_n \in \boldsymbol{\Theta}$, such that (i) $\boldsymbol{\theta}_n \in \partial\boldsymbol{\Theta}$ as $n \to \infty$, and (ii) $\lambda_{\min}(s(\boldsymbol{\theta}_n)) \not\to 0$, $P^*(\boldsymbol{\theta}_n) \to -\infty$

A7) $\sup_{\boldsymbol{\theta}\in\boldsymbol{\Theta}} P^*(\boldsymbol{\theta}) < \infty$

then the set of maximisers is nonempty, i.e.

$$\left\{\boldsymbol{\theta}^* \in \mathrm{int}(\boldsymbol{\Theta}) : \ell^*(\boldsymbol{\theta}^*; \boldsymbol{S}) = \sup_{\boldsymbol{\theta}\in\boldsymbol{\Theta}} \ell^*(\boldsymbol{\theta}; \boldsymbol{S})\right\} \neq \emptyset.$$

Proof. We verify that the conditions of Theorem A1 are met for $\ell^*(\boldsymbol{\theta}; \boldsymbol{S})$.

A1) It is evident that $\ell(\boldsymbol{\Sigma}; \boldsymbol{S})$ is continuous on the space of $p \times p$ positive definite, symmetric matrices. By assumption A4), the map $\boldsymbol{\theta} \mapsto s(\boldsymbol{\theta})$ is continuous so that $\ell(s(\boldsymbol{\theta}); \boldsymbol{S})$ is continuous. Additionally, by A4), $P^*(\boldsymbol{\theta})$ is continuous in $\boldsymbol{\theta}$, so that $\ell^*(\boldsymbol{\theta}; \boldsymbol{S})$ is continuous in $\boldsymbol{\theta}$ on $\boldsymbol{\Theta}$.

A2) Next, let $\mathcal{S}$ be the space of $p \times p$ symmetric nonnegative definite matrices. Burg et al. (1982, Section IV) show that if $\boldsymbol{S}$ is full rank, then $\boldsymbol{S}$ is the unique maximiser of $\ell(\boldsymbol{\Sigma}; \boldsymbol{S})$ over $\mathcal{S}$. Now note that $\mathcal{S}_{\boldsymbol{\theta}} = \{\boldsymbol{\Sigma} : \boldsymbol{\Sigma} = s(\boldsymbol{\theta}), \boldsymbol{\theta} \in \boldsymbol{\Theta}\} \subseteq \mathcal{S}$. Hence,

$$\begin{aligned}
\sup_{\boldsymbol{\theta}\in\boldsymbol{\Theta}} \ell^*(\boldsymbol{\theta}; \boldsymbol{S}) &= \sup_{\boldsymbol{\theta}\in\boldsymbol{\Theta}} \{\ell(s(\boldsymbol{\theta}); \boldsymbol{S}) + P^*(\boldsymbol{\theta})\} \\
&\leq \sup_{\boldsymbol{\Sigma}\in\mathcal{S}_{\boldsymbol{\theta}}} \ell(\boldsymbol{\Sigma}; \boldsymbol{S}) + \sup_{\boldsymbol{\theta}\in\boldsymbol{\Theta}} P^*(\boldsymbol{\theta}) \\
&\leq \sup_{\boldsymbol{\Sigma}\in\mathcal{S}} \ell(\boldsymbol{\Sigma}; \boldsymbol{S}) + \sup_{\boldsymbol{\theta}\in\boldsymbol{\Theta}} P^*(\boldsymbol{\theta}) \\
&= \ell(\boldsymbol{S}; \boldsymbol{S}) + \sup_{\boldsymbol{\theta}\in\boldsymbol{\Theta}} P^*(\boldsymbol{\theta}) \\
&\leq \ell(\boldsymbol{S}; \boldsymbol{S}) + C_p \\
&< \infty,
\end{aligned}$$

where the boundedness of $P^*(\boldsymbol{\theta})$ from above comes from assumption A7).

A3) Consider a sequence $\{\boldsymbol{\theta}_n\}_{n\in\mathbb{N}}$. (i) Assume that $\boldsymbol{\theta}_n \in \boldsymbol{\Theta}$ and $\lambda_{\min}(s(\boldsymbol{\theta}_n)) \not\to 0$, as $n \to \infty$. Then

$$\begin{aligned}
\ell^*(\boldsymbol{\theta}_n; \boldsymbol{S}) &= \ell(s(\boldsymbol{\theta}_n); \boldsymbol{S}) + P^*(\boldsymbol{\theta}_n) \\
&\leq \sup_{\boldsymbol{\Sigma}\in\mathcal{S}} \{\ell(\boldsymbol{\Sigma}; \boldsymbol{S})\} + P^*(\boldsymbol{\theta}_n) \\
&= \ell(\boldsymbol{S}; \boldsymbol{S}) + P^*(\boldsymbol{\theta}_n) \\
&\to -\infty \quad \text{as } n \to \infty,
\end{aligned} \tag{S1}$$

where the last line follows from A5). (ii) Assume that $\boldsymbol{\theta}_n \in \boldsymbol{\Theta}$ and $\lambda_{\min}(s(\boldsymbol{\theta}_n)) \to 0$, as $n \to \infty$. Then Burg et al. (1982, Section II) show that $\ell(s(\boldsymbol{\theta}_n); \boldsymbol{S}) \to -\infty$ as $n \to \infty$. By A7), $\ell^*(s(\boldsymbol{\theta}_n); \boldsymbol{S}) \to -\infty$ as $n \to \infty$. (iii) Assume that $\|\boldsymbol{\theta}_n\| \to \infty$ as $n \to \infty$. If $P^*(\boldsymbol{\theta}_n) \to \infty$, then the bound from (S1) establishes that $\ell^*(\boldsymbol{\theta}_n; \boldsymbol{S}) \to -\infty$. If on the other hand $\|\|s(\boldsymbol{\theta}_n)\|\| \to \infty$, Burg et al. (1982, Section II) show that $\ell(s(\boldsymbol{\theta}_n); \boldsymbol{S}) \to -\infty$ as $n \to \infty$. Therefore

$$\begin{aligned}
\ell^*(\boldsymbol{\theta}_n; \boldsymbol{S}) &= \ell(s(\boldsymbol{\theta}_n); \boldsymbol{S}) + P^*(\boldsymbol{\theta}_n) \\
&\leq \ell(s(\boldsymbol{\theta}_n); \boldsymbol{S})\} + \sup_{\boldsymbol{\theta}\in\boldsymbol{\Theta}} \{P^*(\boldsymbol{\theta}_n)\} \\
&\leq \ell(s(\boldsymbol{\theta}_n); \boldsymbol{S})\} + C_p \\
&\to -\infty \quad \text{as } n \to \infty,
\end{aligned}$$

$\square$

From this result follows the existence of MPL estimates as stated in Theorem 1 in the main text.

Theorem A3 (Existence of MPL estimates in factor analysis)**.** *Let $\partial\Theta = \{\boldsymbol{\theta} \in \Re^{p(q+1)} : \exists m > pq, \theta_m = 0\}$ and $\boldsymbol{\Sigma}(\boldsymbol{\theta}) = \boldsymbol{\Lambda}(\boldsymbol{\theta})\boldsymbol{\Lambda}(\boldsymbol{\theta})^\top + \boldsymbol{\Psi}(\boldsymbol{\theta})$. Assume that the penalty function $P^*(\boldsymbol{\theta}) : \boldsymbol{\Theta} \to \Re$*

E1) is continuous on $\boldsymbol{\Theta}$,

E2) is bounded from above on $\boldsymbol{\Theta}$, i.e. $\sup\limits_{\boldsymbol{\theta}\in\boldsymbol{\Theta}} P^*(\boldsymbol{\theta}) < \infty$, and

E3) diverges to $-\infty$ for any sequence $\{\boldsymbol{\theta}(r)\}_{r\in\mathbb{N}}$ such that $\lim_{r\to\infty} \boldsymbol{\theta}(r) \in \partial\Theta$ and $\lim_{r\to\infty} \lambda_{\min}(\boldsymbol{\Sigma}(\boldsymbol{\theta}(r))) > 0$.

Then, the set of maximum penalized likelihood estimates $\tilde{\boldsymbol{\theta}} \in \arg\max\limits_{\boldsymbol{\theta}\in\boldsymbol{\Theta}} \{\ell^*(\boldsymbol{\theta}; \boldsymbol{S})\}$ is non-empty, when $\boldsymbol{S}$ has full rank.

Proof. We verify that the conditions of Theorem A2 are met for $\boldsymbol{\Theta} = \{\boldsymbol{\theta} \in \Re^{p(q+1)} : \forall i > pq, \theta_i > 0\}$ and $\partial\Theta = \{\boldsymbol{\theta} \in \Re^{p(q+1)} : \exists m > pq, \theta_m = 0\}$ under E1)-E3).

First note that $\partial\Theta$ is the boundary of $\boldsymbol{\Theta}$ and $\mathrm{int}(\boldsymbol{\Theta}) = \boldsymbol{\Theta}$. Further recall, that $\boldsymbol{\theta} \mapsto \boldsymbol{\Sigma}(\boldsymbol{\theta})$ for $\boldsymbol{\Sigma} = \boldsymbol{\Lambda}\boldsymbol{\Lambda}^\top + \boldsymbol{\Psi}$ for $\boldsymbol{\theta} = (\theta_1, \ldots, \theta_{p(q+1)})^\top = (\lambda_{11}, \ldots, \lambda_{pq}, \psi_{11}, \ldots, \psi_{pp})^\top$, where λ_{jk} and ψ_{jj} are the (j,k)th and (j,j)th elements of $\boldsymbol{\Lambda}$ and $\boldsymbol{\Psi}$, respectively $(j = 1, \ldots, p; k = 1, \ldots, q)$. Thus, for each $\boldsymbol{\theta} \in \boldsymbol{\Theta}$, $\boldsymbol{\Sigma}$ is positive definite.

It remains to verify assumptions A4)-A7).

A4) It is readily seen that $\boldsymbol{\theta} \mapsto \boldsymbol{\Sigma}(\boldsymbol{\theta})$ is continuous on $\boldsymbol{\Theta}$. Further, P^* is continuous by assumption E1).

A5) Let $\boldsymbol{\theta}(r)$ be a diverging sequence in $\boldsymbol{\Theta}$ as $r \to \infty$ and $\boldsymbol{\Sigma}(r)$ the associated sequence of variance-covariance matrices. The ith element of $\boldsymbol{\Sigma}(r)$ is given by

$$\boldsymbol{\Sigma}(r)_{ii} = \sum_{j=1} \lambda_{ij}(r)^2 + \psi_{ii}(r).$$

Hence if either $|\lambda_{ij}(r)| \to \infty$ or $\psi_{ii}(r) \to \infty$ as $r \to \infty$, also $\boldsymbol{\Sigma}_{ii}(r) \to \infty$ and consequently $\|\|\boldsymbol{\Sigma}(r)\|\| \to \infty$ as required.

A6) Holds by E3).

A7) Holds by E2).

This concludes the proof. $\square$

S2.2 Consistency

As we did for existence, and for the same reasons, we first provide a consistency result for general parameter spaces $\boldsymbol{\Theta}$. From this, the existence result of Theorem 2 follows as a corollary. These more general parameterisations are for example required for the $\sqrt{n}$-consistency results of Section 5.2 and they might be desirable if one wishes to impose further restrictions on the structure of $\boldsymbol{\Sigma}$.

Theorem A4. *Let $\boldsymbol{\Theta} \subseteq \Re^d$, denote by $cl(\boldsymbol{\Theta})$ its closure, $\partial\Theta$ a set of sequential limit points of $\boldsymbol{\Theta}$ and denote by $\mathrm{int}(\boldsymbol{\Theta}) = cl(\boldsymbol{\Theta}) \setminus \partial\Theta$. Let $\boldsymbol{\Sigma}(\boldsymbol{\theta}) = \boldsymbol{\Lambda}(\boldsymbol{\theta})\boldsymbol{\Lambda}(\boldsymbol{\theta})^\top + \boldsymbol{\Psi}(\boldsymbol{\theta})$ for some maps $\boldsymbol{\theta} \mapsto \boldsymbol{\Lambda}(\boldsymbol{\theta})$, $\boldsymbol{\theta} \mapsto \boldsymbol{\Psi}(\boldsymbol{\theta})$. Finally, denote by $\ell^*(\boldsymbol{\theta}; \boldsymbol{S}) = \ell(\boldsymbol{\Sigma}(\boldsymbol{\theta}); \boldsymbol{S}) + P^*(\boldsymbol{\theta})$ the profile log-likelihood of the EFA model in Section 2.*

Assume that

A8) the factor model is strongly identifiable

A9) There exists a $\boldsymbol{\theta}_0 \in \mathrm{int}(\boldsymbol{\Theta})$ such that $\boldsymbol{\Sigma}(\boldsymbol{\theta}_0) = \boldsymbol{\Sigma}_0$

A10)
$$\left\{ \boldsymbol{\theta}^* \in \text{int}(\boldsymbol{\Theta}) : \ell^*(\boldsymbol{\theta}^*; \boldsymbol{S}) = \sup_{\boldsymbol{\theta} \in \boldsymbol{\Theta}} \ell^*(\boldsymbol{\theta}; \boldsymbol{S}) \right\} \neq \emptyset \, .$$

A11) $P^*(\boldsymbol{\theta}) \leq 0$ for all $\boldsymbol{\theta} \in \boldsymbol{\Theta}$

Then for any $\epsilon > 0$ there exists a $\delta > 0$ such that

$$\left|\left|\left| \boldsymbol{S} - \boldsymbol{\Sigma}_0 \right|\right|\right|_{\max} < \delta \, , \text{and} \, |n^{-1} P^*(\boldsymbol{\theta}_0)| < \delta \implies \left|\left|\left| \boldsymbol{\Lambda}_0 - \boldsymbol{\Lambda}(\tilde{\boldsymbol{\theta}}) \boldsymbol{Q} \right|\right|\right|_{\max} < \epsilon, \left|\left|\left| \boldsymbol{\Psi}_0 - \boldsymbol{\Psi}(\tilde{\boldsymbol{\theta}}) \right|\right|\right|_{\max} < \epsilon,$$

for some orthogonal $q \times q$ matrix $\boldsymbol{Q}$.

Proof. The proof follows the ideas of Kano (1983) whilst accommodating the penalty function $P^*(\boldsymbol{\theta})$. First, note that the MPL estimator of (4) can equivalently be defined as the minimiser

$$\tilde{\boldsymbol{\theta}} = \arg\min_{\boldsymbol{\theta} \in \boldsymbol{\Theta}} \left\{ F(\boldsymbol{S}, \boldsymbol{\Sigma}(\boldsymbol{\theta})) - n^{-1} P^*(\boldsymbol{\theta}) \right\} \, , \tag{S2}$$

where

$$F(\boldsymbol{\Sigma}_1, \boldsymbol{\Sigma}_2) = \frac{1}{2} \left\{ \text{tr} \left(\boldsymbol{\Sigma}_2^{-1} \boldsymbol{\Sigma}_1 \right) - p + \log \det (\boldsymbol{\Sigma}_2) - \log \det (\boldsymbol{\Sigma}_1) \right\}$$

is a criterion function that introduced in Kano (1983).

For notational convenience, let $\tilde{\boldsymbol{\Sigma}} = \boldsymbol{\Sigma}(\tilde{\boldsymbol{\theta}}) = \boldsymbol{\Lambda}(\tilde{\boldsymbol{\theta}}) \boldsymbol{\Lambda}(\tilde{\boldsymbol{\theta}})^\top + \boldsymbol{\Psi}(\tilde{\boldsymbol{\theta}})$. Now by (S2), and since $P^*(\boldsymbol{\theta}) \leq 0$, $|n^{-1} P^*(\boldsymbol{\theta}_0)| < \delta$, it must hold that

$$F(\boldsymbol{S}, \tilde{\boldsymbol{\Sigma}}) \leq F(\boldsymbol{S}, \tilde{\boldsymbol{\Sigma}}) - n^{-1} P^*(\tilde{\boldsymbol{\theta}}) \leq F(\boldsymbol{S}, \boldsymbol{\Sigma}_0) - n^{-1} P^*(\boldsymbol{\theta}_0) \leq F(\boldsymbol{S}, \boldsymbol{\Sigma}_0) + \delta \, . \tag{S3}$$

Now for $\left|\left|\left| \boldsymbol{S} - \boldsymbol{\Sigma}_0 \right|\right|\right|_F \leq \delta$ and δ small enough, where $\left|\left|\left| \boldsymbol{A} \right|\right|\right|_F = \text{tr} \left(\boldsymbol{A}^\top \boldsymbol{A} \right)^{1/2}$ is the Frobenius norm, it is shown in Kano (1983, equations A.2, A.4), that

$$F(\boldsymbol{S}, \boldsymbol{\Sigma}_0) \leq M \left|\left|\left| \boldsymbol{\Sigma}_0^{-1/2} \right|\right|\right|_F^4 \left|\left|\left| \boldsymbol{\Sigma}_0 - \boldsymbol{S} \right|\right|\right|_F^2 < M \left|\left|\left| \boldsymbol{\Sigma}_0^{-1/2} \right|\right|\right|_F^4 \delta^2 \, ,$$

and also

$$F(\boldsymbol{S}, \tilde{\boldsymbol{\Sigma}}) \geq m \left|\left|\left| \tilde{\boldsymbol{\Sigma}}^{-1/2} \boldsymbol{S} \tilde{\boldsymbol{\Sigma}}^{-1/2} - \boldsymbol{I}_p \right|\right|\right|_F^2 \geq m \left|\left|\left| \boldsymbol{S} - \tilde{\boldsymbol{\Sigma}} \right|\right|\right|_F^2 \left|\left|\left| \tilde{\boldsymbol{\Sigma}}^{1/2} \right|\right|\right|_F^{-4} \, . \tag{S4}$$

Hence, (S3)-(S4) yield

$$m \left|\left|\left| \boldsymbol{S} - \tilde{\boldsymbol{\Sigma}} \right|\right|\right|_F^2 \left|\left|\left| \tilde{\boldsymbol{\Sigma}}^{1/2} \right|\right|\right|_F^{-4} \leq m \left|\left|\left| \tilde{\boldsymbol{\Sigma}}^{-1/2} \boldsymbol{S} \tilde{\boldsymbol{\Sigma}}^{-1/2} - \boldsymbol{I}_p \right|\right|\right|_F^2 \leq \delta \left(1 + \delta M \left|\left|\left| \boldsymbol{\Sigma}_0^{-1/2} \right|\right|\right|_F^4 \right) \, . \tag{S5}$$

It further holds by (S5) and for $\left|\left|\left| \boldsymbol{S} - \boldsymbol{\Sigma}_0 \right|\right|\right|_{\max} \leq \delta$, δ sufficiently small, that $\left|\left|\left| \tilde{\boldsymbol{\Sigma}}^{1/2} \right|\right|\right|_F \leq C$ for some constant $C > 0$. Thus we conclude that

$$\left|\left|\left| \boldsymbol{S} - \tilde{\boldsymbol{\Sigma}} \right|\right|\right|_F^2 \leq \delta \left(1 + \delta M \left|\left|\left| \boldsymbol{\Sigma}_0^{-1/2} \right|\right|\right|_F^4 \right) m^{-1} C^4 \, ,$$

which can be made arbitrarily small by choosing a small enough δ. Hence,

$$\begin{aligned} \left|\left|\left| \tilde{\boldsymbol{\Sigma}} - \boldsymbol{\Sigma}_0 \right|\right|\right|_{\max} &= \left|\left|\left| \tilde{\boldsymbol{\Sigma}} - \boldsymbol{S} + (\boldsymbol{S} - \boldsymbol{\Sigma}_0) \right|\right|\right|_{\max} \\ &\leq \left|\left|\left| \tilde{\boldsymbol{\Sigma}} - \boldsymbol{S} \right|\right|\right|_{\max} + \left|\left|\left| \boldsymbol{S} - \boldsymbol{\Sigma}_0 \right|\right|\right|_{\max} \\ &\leq C' \delta + \delta \, , \end{aligned} \tag{S6}$$

where $C' > 0$ stems from (S5) and $\left|\left|\left| \boldsymbol{A} \right|\right|\right|_F = \sqrt{\sum_{i,j} |\boldsymbol{A}_{i,j}|^2} \geq \max_{i,j} \{|\boldsymbol{A}_{i,j}|\} = \left|\left|\left| \boldsymbol{A} \right|\right|\right|_{\max}$. Since the RHS in the last line of (S6) can be made arbitrarily small, the claim follows from $\tilde{\boldsymbol{\Sigma}} = \boldsymbol{\Sigma}(\tilde{\boldsymbol{\theta}}) = \boldsymbol{\Lambda}(\tilde{\boldsymbol{\theta}}) \boldsymbol{\Lambda}(\tilde{\boldsymbol{\theta}})^\top + \boldsymbol{\Psi}(\tilde{\boldsymbol{\theta}})$, strong identifiability. □

9

Theorem A5. *Assume that*

C1) the factor model is strongly identifiable

C2) the set of maximum penalized likelihood estimates $\tilde{\boldsymbol{\theta}} \in \arg\max_{\boldsymbol{\theta} \in \boldsymbol{\Theta}} \{\ell^*(\boldsymbol{\theta}; S)\}$ is non-empty; and

C3) $P^*(\boldsymbol{\theta}) \leq 0$ for all $\boldsymbol{\theta} \in \boldsymbol{\Theta}$

   Then, for any $\epsilon > 0$, there exists a $\delta > 0$ such that

$$\left\|\boldsymbol{S} - \boldsymbol{\Sigma}_0\right\|_{\max} < \delta\,,\text{and } |n^{-1}P^*(\boldsymbol{\theta}_0)| < \delta \implies \left\|\boldsymbol{\Lambda}_0 - \boldsymbol{\Lambda}(\tilde{\boldsymbol{\theta}})\boldsymbol{Q}\right\|_{\max} < \epsilon\,, \left\|\boldsymbol{\Psi}_0 - \boldsymbol{\Psi}(\tilde{\boldsymbol{\theta}})\right\|_{\max} < \epsilon\,,$$

for some orthogonal $q \times q$ matrix $\boldsymbol{Q}$.

Proof. Let $\boldsymbol{\Theta} = \{\boldsymbol{\theta} \in \Re^{p(q+1)} : \forall m > pq, \theta_m > 0\}$ and $\partial\boldsymbol{\Theta} = \{\boldsymbol{\theta} \in \Re^{p(q+1)} : \exists m > pq, \theta_m = 0\}$ be its boundary. The claim of the theorem immediately follows from Theorem A4. $\qquad\square$

S2.3 $\sqrt{n}$-consistency

We first state a blanket theorem for $\sqrt{n}$-consistency of MPL estimators, from which Theorem 3 follows.

Theorem A6. *Let*

$$\tilde{\boldsymbol{\theta}} \in \arg\max_{\boldsymbol{\theta} \in \boldsymbol{\Theta}} \{\ell(\boldsymbol{\theta}) + P^*(\boldsymbol{\theta})\}\,, \quad \hat{\boldsymbol{\theta}} \in \arg\max_{\boldsymbol{\theta} \in \boldsymbol{\Theta}} \{\ell(\boldsymbol{\theta})\}\,.$$

Assume that conditions the conditions

A12) $\hat{\boldsymbol{\theta}}, \tilde{\boldsymbol{\theta}}$ exist and converge to $\boldsymbol{\theta}_0$, an interior point of $\boldsymbol{\Theta}$, with probability approaching one as $n \to \infty$

A13) In a convex neighbourhood $\mathcal{N}_0$ around $\boldsymbol{\theta}_0$, $\ell(\boldsymbol{\theta})$ is twice differentiable with gradient that is continuous on an open set containing the interior of $\mathcal{N}_0$

A14) $\sup_{\boldsymbol{\theta} \in \mathcal{N}_0} \left\|\boldsymbol{R}_n^{-1/2}\nabla\nabla^\top\ell(\boldsymbol{\theta})\boldsymbol{R}_n^{-1/2} - \boldsymbol{J}(\boldsymbol{\theta})\right\| = o_p(1)$, where $\boldsymbol{J}(\boldsymbol{\theta})$ is deterministic, continuous and invertible at $\boldsymbol{\theta}_0$ and $\boldsymbol{R}_n$ is a sequence of diagonal, positive definite matrices indexed by n

A15) $P^*(\boldsymbol{\theta})$ is differentiable on $\mathcal{N}_0$ around $\boldsymbol{\theta}_0$, and $\sup_{\boldsymbol{\theta} \in \mathcal{N}_0} \|\boldsymbol{R}_n^{-1/2}\nabla P^*(\boldsymbol{\theta})\| = o_p(1)$

   hold. Then

$$\left\|\boldsymbol{R}_n^{1/2}(\hat{\boldsymbol{\theta}} - \tilde{\boldsymbol{\theta}})\right\| = o_p(1)\,.$$

Proof. By the equivalence of norms on finite dimensional Euclidean spaces, without loss of generality, for the remainder of this proof, let $\|\boldsymbol{v}\| = \|\boldsymbol{v}\|_\infty = \sup_{1 \leq i \leq d}|\boldsymbol{v}_i|$ and $\|\boldsymbol{M}\| = \|\boldsymbol{M}\|_\infty$ be the corresponding operator norm.

   Fix constants ϵ, δ. Define the events

$\mathcal{A}_n$: $\hat{\boldsymbol{\theta}}, \tilde{\boldsymbol{\theta}} \in \text{int}(\boldsymbol{\Theta}) \cap \mathcal{N}_0 \cap B_\varepsilon(\boldsymbol{\theta}_0)$, where ε is the constant for which by continuity of $\boldsymbol{J}(\boldsymbol{\theta}_0)$, it holds that $\|\boldsymbol{\theta} - \boldsymbol{\theta}_0\| < \varepsilon$ implies $\|\boldsymbol{J}(\boldsymbol{\theta}) - \boldsymbol{J}(\boldsymbol{\theta}_0)\| < \{4\|\boldsymbol{J}(\boldsymbol{\theta}_0)^{-1}\|\}^{-1}$ and $B_\varepsilon(\boldsymbol{\theta}_0) = \{\boldsymbol{\theta} \in \boldsymbol{\Theta} : \|\boldsymbol{\theta} - \boldsymbol{\theta}_0\| < \varepsilon\}$.

$\mathcal{B}_n$: $\sup_{\boldsymbol{\theta} \in \mathcal{N}_0} \|\boldsymbol{H}_n(\boldsymbol{\theta}) - \boldsymbol{J}(\boldsymbol{\theta})\| \leq \{4\|\boldsymbol{J}(\boldsymbol{\theta}_0)^{-1}\|\}^{-1}$, where $\boldsymbol{H}_n = \boldsymbol{R}_n^{-1/2}\nabla\nabla^\top\ell(\boldsymbol{\theta})\boldsymbol{R}_n^{-1/2}$

$\mathcal{C}_n$: $P^*(\boldsymbol{\theta})$ is differentiable in $\mathcal{N}_0$ and $\sup_{\boldsymbol{\theta} \in \mathcal{N}_0} \|\boldsymbol{R}_n^{-1/2}\nabla P^*(\boldsymbol{\theta})\| \leq \epsilon/2\|\boldsymbol{J}(\boldsymbol{\theta}_0)^{-1}\|$.

Assume that $\mathcal{A}_n \cap \mathcal{B}_n \cap \mathcal{C}_n$ holds. Then by $\mathcal{A}_n$, and assumptions A13) and A15),

$$\mathbf{0} = \nabla\ell(\hat{\boldsymbol{\theta}})$$
$$\mathbf{0} = \nabla\ell(\tilde{\boldsymbol{\theta}}) + \nabla P^*(\tilde{\boldsymbol{\theta}}),$$

where $\nabla\ell(\boldsymbol{\theta})$ denotes the gradient of $\ell(\boldsymbol{\theta})$ with respect to $\boldsymbol{\theta}$. Thus,

$$\nabla\ell(\hat{\boldsymbol{\theta}}) - \nabla\ell(\tilde{\boldsymbol{\theta}}) = \nabla P^*(\tilde{\boldsymbol{\theta}}).$$

By the Mean Value Theorem (see, for example, Rudin, 1976, Theorem 5.10), the ith component of the equation above can be written as

$$\left\{\nabla\nabla^\top\ell(\boldsymbol{\theta}_i^*)\right\}_{i,\bullet}^\top (\hat{\boldsymbol{\theta}} - \tilde{\boldsymbol{\theta}}) = \left\{\nabla P^*(\tilde{\boldsymbol{\theta}})\right\}_i,$$

where $\{\boldsymbol{A}\}_{i,\bullet}$ denotes the ith row of matrix $\boldsymbol{A}$ and $\boldsymbol{\theta}_i^*$ is a vector on the line segment joining $\hat{\boldsymbol{\theta}}$ and $\tilde{\boldsymbol{\theta}}$, i.e. $\boldsymbol{\theta}_i^* = c_i\hat{\boldsymbol{\theta}} + (1 - c_i)\tilde{\boldsymbol{\theta}}$, $c_i \in [0,1]$. Abusing notation, let $\nabla\nabla^\top\ell(\boldsymbol{\theta}^*)$ be the matrix with rows $\left\{\nabla\nabla^\top\ell(\boldsymbol{\theta}_i^*)\right\}_{i,\bullet}$ and let $\boldsymbol{H}_n = \boldsymbol{R}_n^{-1/2}\nabla\nabla^\top\ell(\boldsymbol{\theta}^*)\boldsymbol{R}_n^{-1/2}$. Then

$$\boldsymbol{J}(\boldsymbol{\theta}_0)^{-1}\boldsymbol{H}_n\boldsymbol{R}_n^{1/2}(\hat{\boldsymbol{\theta}} - \tilde{\boldsymbol{\theta}}) = \boldsymbol{J}(\boldsymbol{\theta}_0)^{-1}\boldsymbol{R}_n^{-1/2}\nabla P^*(\tilde{\boldsymbol{\theta}}),$$

or equivalently

$$\boldsymbol{J}(\boldsymbol{\theta}_0)^{-1}\left\{\boldsymbol{H}_n - \boldsymbol{J}(\boldsymbol{\theta}_0)\right\}\boldsymbol{R}_n^{1/2}(\hat{\boldsymbol{\theta}} - \tilde{\boldsymbol{\theta}}) + \boldsymbol{R}_n^{1/2}(\hat{\boldsymbol{\theta}} - \tilde{\boldsymbol{\theta}}) = \boldsymbol{J}(\boldsymbol{\theta}_0)^{-1}\boldsymbol{R}_n^{-1/2}\nabla P^*(\tilde{\boldsymbol{\theta}}),$$

and rearranging yields

$$\boldsymbol{R}_n^{1/2}(\hat{\boldsymbol{\theta}} - \tilde{\boldsymbol{\theta}}) = \boldsymbol{J}(\boldsymbol{\theta}_0)^{-1}\boldsymbol{R}_n^{-1/2}\nabla P^*(\tilde{\boldsymbol{\theta}}) + \boldsymbol{J}(\boldsymbol{\theta}_0)^{-1}\left\{\boldsymbol{J}(\boldsymbol{\theta}_0) - \boldsymbol{H}_n\right\}\boldsymbol{R}_n^{1/2}(\hat{\boldsymbol{\theta}} - \tilde{\boldsymbol{\theta}}).$$

Then

$$\begin{aligned}
\left\|\boldsymbol{R}_n^{1/2}(\hat{\boldsymbol{\theta}} - \tilde{\boldsymbol{\theta}})\right\| &= \left\|\boldsymbol{J}(\boldsymbol{\theta}_0)^{-1}\boldsymbol{R}_n^{-1/2}\nabla P^*(\tilde{\boldsymbol{\theta}}) + \boldsymbol{J}(\boldsymbol{\theta}_0)^{-1}\left\{\boldsymbol{J}(\boldsymbol{\theta}_0) - \boldsymbol{H}_n\right\}\boldsymbol{R}_n^{1/2}(\hat{\boldsymbol{\theta}} - \tilde{\boldsymbol{\theta}})\right\| \\
&\le \left\|\|\boldsymbol{J}(\boldsymbol{\theta}_0)^{-1}\|\right\|\left\|\boldsymbol{R}_n^{-1/2}\nabla P^*(\tilde{\boldsymbol{\theta}})\right\| + \left\|\|\boldsymbol{J}(\boldsymbol{\theta}_0)^{-1}\|\right\|\left\|\|\boldsymbol{J}(\boldsymbol{\theta}_0) - \boldsymbol{H}_n\|\right\|\left\|\boldsymbol{R}_n^{1/2}(\hat{\boldsymbol{\theta}} - \tilde{\boldsymbol{\theta}})\right\|.
\end{aligned} \tag{S7}$$

Now let i be the row for which the row sum of $\boldsymbol{J}(\boldsymbol{\theta}_0) - \boldsymbol{H}_n$ is maximal, then by $\mathcal{A}_n$, $\mathcal{B}_n$,

$$\begin{aligned}
\left\|\|\boldsymbol{J}(\boldsymbol{\theta}_0) - \boldsymbol{H}_n\|\right\| &= \sum_{j=1}^p |\boldsymbol{J}(\boldsymbol{\theta}_0)_{ij} - \boldsymbol{H}_n(\boldsymbol{\theta}_i^*)_{ij}| \\
&= \sum_{j=1}^p |\boldsymbol{J}(\boldsymbol{\theta}_0)_{ij} - \boldsymbol{J}(\boldsymbol{\theta}_i^*)_{ij} + \boldsymbol{J}(\boldsymbol{\theta}_i^*)_{ij} - \boldsymbol{H}_n(\boldsymbol{\theta}_i^*)_{ij}| \\
&\le \sum_{j=1}^p |\boldsymbol{J}(\boldsymbol{\theta}_0)_{ij} - \boldsymbol{J}(\boldsymbol{\theta}_i^*)_{ij}| + \sum_{j=1}^p |\boldsymbol{J}(\boldsymbol{\theta}_i^*)_{ij} - \boldsymbol{H}_n(\boldsymbol{\theta}_i^*)_{ij}| \\
&\le \sup_{1\le k\le p}\sum_{j=1}^p |\boldsymbol{J}(\boldsymbol{\theta}_0)_{kj} - \boldsymbol{J}(\boldsymbol{\theta}_i^*)_{kj}| + \sup_{1\le k\le p}\sum_{j=1}^p |\boldsymbol{J}(\boldsymbol{\theta}_i^*)_{kj} - \boldsymbol{H}_n(\boldsymbol{\theta}_i^*)_{kj}| \\
&= \left\|\|\boldsymbol{J}(\boldsymbol{\theta}_0) - \boldsymbol{J}(\boldsymbol{\theta}_i^*)\|\right\| + \left\|\|\boldsymbol{J}(\boldsymbol{\theta}_i^*) - \boldsymbol{H}_n(\boldsymbol{\theta}_i^*)\|\right\| \\
&\le \left\|\|\boldsymbol{J}(\boldsymbol{\theta}_0) - \boldsymbol{J}(\boldsymbol{\theta}_i^*)\|\right\| + \sup_{\boldsymbol{\theta}\in\mathcal{N}_0}\left\|\|\boldsymbol{J}(\boldsymbol{\theta}) - \boldsymbol{H}_n(\boldsymbol{\theta})\|\right\| \\
&\le \frac{1}{4\|\|\boldsymbol{J}(\boldsymbol{\theta}_0)^{-1}\|\|} + \frac{1}{4\|\|\boldsymbol{J}(\boldsymbol{\theta}_0)^{-1}\|\|} \\
&= \frac{1}{2\|\|\boldsymbol{J}(\boldsymbol{\theta}_0)^{-1}\|\|},
\end{aligned} \tag{S8}$$

where we used that $\mathcal{A}_n$ and that $\boldsymbol{\theta}_i = c_i\hat{\boldsymbol{\theta}} + (1 - c_i)\tilde{\boldsymbol{\theta}}$ so $\|\boldsymbol{\theta}_i^* - \boldsymbol{\theta}_0\| \le c_i\|\hat{\boldsymbol{\theta}} - \boldsymbol{\theta}_0\| + (1 - c_i)\|\tilde{\boldsymbol{\theta}} - \boldsymbol{\theta}_0\| < \varepsilon$.

Hence, substituting (S8) into (S7), upon rearranging, yields

$$\left\| \boldsymbol{R}_n^{1/2}(\hat{\boldsymbol{\theta}} - \tilde{\boldsymbol{\theta}}) \right\| \le 2\left\|\left|\boldsymbol{J}(\boldsymbol{\theta}_0)^{-1}\right\|\right\| \left\| \boldsymbol{R}_n^{-1/2}\nabla P^*(\tilde{\boldsymbol{\theta}}) \right\| ,$$

and by $\mathcal{C}_n$, we conclude that

$$
\begin{aligned}
\left\| \boldsymbol{R}_n^{1/2}(\hat{\boldsymbol{\theta}} - \tilde{\boldsymbol{\theta}}) \right\| &\le 2\left\|\left|\boldsymbol{J}(\boldsymbol{\theta}_0)^{-1}\right\|\right\| \left\| \boldsymbol{R}_n^{-1/2}\nabla P^*(\tilde{\boldsymbol{\theta}}) \right\| \\
&\le 2\left\|\left|\boldsymbol{J}(\boldsymbol{\theta}_0)^{-1}\right\|\right\| \sup_{\boldsymbol{\theta}\in\mathcal{N}_0} \left\| \boldsymbol{R}_n^{-1/2}\nabla P^*(\boldsymbol{\theta}) \right\| \\
&\le 2\left\|\left|\boldsymbol{J}(\boldsymbol{\theta}_0)^{-1}\right\|\right\| \frac{\epsilon}{2\left\|\left|\boldsymbol{J}(\boldsymbol{\theta}_0)^{-1}\right\|\right\|} \\
&= \epsilon .
\end{aligned}
$$

Hence, we have shown that $\mathcal{A}_n \cap \mathcal{B}_n \cap \mathcal{C}_n$ implies $\|\boldsymbol{R}_n^{1/2}(\hat{\boldsymbol{\theta}} - \tilde{\boldsymbol{\theta}})\| \le \epsilon$. Therefore,

$$\Pr\left(\left\| \boldsymbol{R}_n^{1/2}(\hat{\boldsymbol{\theta}} - \tilde{\boldsymbol{\theta}}) \right\| > \epsilon\right) \le 1 - \Pr(\mathcal{A}_n \cap \mathcal{B}_n \cap \mathcal{C}_n) .$$

By assumptions A12)-A15), there exists a N such that for all $n > N$,

$$
\begin{aligned}
\Pr(\neg\mathcal{A}_n) &\le \frac{\delta}{3} \\
\Pr(\neg\mathcal{B}_n) &\le \frac{\delta}{3} \\
\Pr(\neg\mathcal{C}_n) &\le \frac{\delta}{3} ,
\end{aligned}
$$

And thus by a union bound,

$$\Pr(\mathcal{A}_n \cap \mathcal{B}_n \cap \mathcal{C}_n) = 1 - \Pr(\neg\mathcal{A}_n \cup \neg\mathcal{B}_n \cup \neg\mathcal{C}_n) \ge 1 - \delta ,$$

so that we conclude that for any δ, ϵ, there is a N such that for all $n > N$

$$\Pr\left(\left\| \boldsymbol{R}_n^{1/2}(\hat{\boldsymbol{\theta}} - \tilde{\boldsymbol{\theta}}) \right\| > \epsilon\right) \le \delta .$$

$\square$

Theorem A7. *Suppose that*

N1) there exists an interior point $\boldsymbol{\theta}_0 \in \boldsymbol{\Theta}$ such that $\boldsymbol{S} \xrightarrow{p} \boldsymbol{\Sigma}(\boldsymbol{\theta}_0)$ as $n \to \infty$;

N2) the factor model is strongly identifiable and the Jacobian of $vec(\boldsymbol{\Sigma}(\boldsymbol{\theta}))$ with respect to $\boldsymbol{\theta}$ is nonsingular at $\boldsymbol{\theta}_0$;

N3) the criterion function

$$F(\boldsymbol{\Sigma}_1, \boldsymbol{\Sigma}_2) = \log\det(\boldsymbol{\Sigma}_2) + tr\left(\boldsymbol{\Sigma}_2^{-1}\boldsymbol{\Sigma}_1\right) - p - \log\det(\boldsymbol{\Sigma}_1)$$

satisfies that for any $\epsilon > 0$, there exists a $\delta > 0$ such that if $\|\|\boldsymbol{S} - \boldsymbol{\Sigma}_0\|\| < \delta$ and $F(\boldsymbol{S}, \boldsymbol{\Sigma}(\boldsymbol{\theta})) < \delta$, then $\|\|\boldsymbol{\Sigma}(\boldsymbol{\theta}) - \boldsymbol{\Sigma}_0\|\| < \epsilon$.

N4) the set of maximum penalized likelihood estimates $\tilde{\boldsymbol{\theta}} \in \arg\max_{\boldsymbol{\theta}\in\boldsymbol{\Theta}}\{\ell^*(\boldsymbol{\theta}; S)\}$ is not empty; and

N5) $P^*(\boldsymbol{\theta}) \le 0$, and $P^*(\boldsymbol{\theta}) = o_p(\sqrt{n})$ where $P(\boldsymbol{\theta})$ is continuously differentiable on $\boldsymbol{\Theta}$ and invariant under orthogonal rotations of $\boldsymbol{\Lambda}$

Then, there exist sequences of orthogonal rotation matrices $\boldsymbol{Q}_1, \boldsymbol{Q}_2$ such that:

$$\left\|\left\|\boldsymbol{\Lambda}(\tilde{\boldsymbol{\theta}})\boldsymbol{Q}_1 - \boldsymbol{\Lambda}_0\right\|\right\| \xrightarrow{p} 0, \quad \left\|\left\|\boldsymbol{\Psi}(\tilde{\boldsymbol{\theta}}) - \boldsymbol{\Psi}_0\right\|\right\| \xrightarrow{p} 0,$$

and

$$\sqrt{n}\left\|\left\|\boldsymbol{\Lambda}(\tilde{\boldsymbol{\theta}})\boldsymbol{Q}_1 - \boldsymbol{\Lambda}(\hat{\boldsymbol{\theta}})\boldsymbol{Q}_2\right\|\right\| \xrightarrow{p} 0, \quad \sqrt{n}\left\|\left\|\boldsymbol{\Psi}(\tilde{\boldsymbol{\theta}}) - \boldsymbol{\Psi}(\hat{\boldsymbol{\theta}})\right\|\right\| \xrightarrow{p} 0.$$

Proof. We shall prove that the conditions of Theorem A6 are met.

A12) Let $\hat{\boldsymbol{\Lambda}}, \hat{\boldsymbol{\Psi}}$ be $\boldsymbol{\Lambda}(\hat{\boldsymbol{\theta}}), \boldsymbol{\Psi}(\hat{\boldsymbol{\theta}})$, be the loading matrix and the variances of the ML estimator $\hat{\boldsymbol{\theta}}$, respectively. Lemma 1 shows that there exists a sequence of orthogonal rotation matrices $\boldsymbol{Q}_1$, such that $\{\text{vec}(\hat{\boldsymbol{\Lambda}}\boldsymbol{Q}_1), \text{diag}(\hat{\boldsymbol{\Psi}})\} \xrightarrow{p} \boldsymbol{\theta}_0 = (\text{vec}(\boldsymbol{\Lambda}_0)^\top, \text{diag}(\boldsymbol{\Psi}_0)^\top)^\top$. Since this vector is also a maximiser of the log-likelihood, we henceforth assume that $\hat{\boldsymbol{\theta}}$ is chosen with the adequate rotation $\boldsymbol{Q}_1$ such that $\hat{\boldsymbol{\theta}} \xrightarrow{p} \boldsymbol{\theta}_0$. Similarly, for the MPL estimator $\tilde{\boldsymbol{\theta}}$, note that assumptions N1)-N5) satisfy the conditions for consistency in Theorem A4. Hence, there exists a sequence of orthogonal rotation matrices $\boldsymbol{Q}_2$, such that $\{\text{vec}(\tilde{\boldsymbol{\Lambda}}\boldsymbol{Q}_2), \text{diag}(\tilde{\boldsymbol{\Psi}})\} \xrightarrow{p} \boldsymbol{\theta}_0$. By assumption N5), $P(\boldsymbol{\theta})$ is invariant under such orthogonal rotations, so that $\{\text{vec}(\tilde{\boldsymbol{\Lambda}}\boldsymbol{Q}_2), \text{diag}(\tilde{\boldsymbol{\Psi}})\}$ is also a maximiser of the penalised log-likelihood. Thus, henceforth assume that $\tilde{\boldsymbol{\theta}}$ chooses the adequate rotation $\boldsymbol{Q}_2$ such that $\tilde{\boldsymbol{\theta}} \xrightarrow{p} \boldsymbol{\theta}_0$.

A13) Twice-Differentiability follows by twice-differentiability of $\ell(\boldsymbol{\Sigma}; \boldsymbol{S})$ with respect to $\boldsymbol{\Sigma}$ and the construction of $\boldsymbol{\Sigma}$. Note that the partial derivatives are given by

$$\frac{\partial \ell(\boldsymbol{\Sigma}(\boldsymbol{\theta}); \boldsymbol{S})}{\partial \boldsymbol{\theta}_j} = -\frac{n}{2}\left[\text{tr}\left\{\boldsymbol{\Sigma}(\boldsymbol{\theta})^{-1}\frac{\partial \boldsymbol{\Sigma}(\boldsymbol{\theta})}{\partial \boldsymbol{\theta}_j}\right\} - \text{tr}\left\{\boldsymbol{\Sigma}(\boldsymbol{\theta})^{-1}\frac{\partial \boldsymbol{\Sigma}(\boldsymbol{\theta})}{\partial \boldsymbol{\theta}_j}\boldsymbol{\Sigma}(\boldsymbol{\theta})^{-1}\boldsymbol{S}\right\}\right]$$

which are continuous in $\boldsymbol{\Sigma}$ and $\boldsymbol{\Sigma}(\boldsymbol{\theta})$ is continuous in $\boldsymbol{\theta}$ on $\boldsymbol{\Theta}$ by N2).

A14) Note that

$$\begin{aligned}
\frac{\partial^2 \ell(\boldsymbol{\Sigma}(\boldsymbol{\theta}); \boldsymbol{S})}{\partial \boldsymbol{\theta}_j \partial \boldsymbol{\theta}_k} = -\frac{n}{2}\Bigg[&-\text{tr}\left\{\boldsymbol{\Sigma}(\boldsymbol{\theta})^{-1}\frac{\partial \boldsymbol{\Sigma}(\boldsymbol{\theta})}{\partial \boldsymbol{\theta}_j}\boldsymbol{\Sigma}(\boldsymbol{\theta})^{-1}\frac{\partial \boldsymbol{\Sigma}(\boldsymbol{\theta})}{\partial \boldsymbol{\theta}_i}\right\} \\
&+ \text{tr}\left\{\boldsymbol{\Sigma}(\boldsymbol{\theta})^{-1}\frac{\partial^2 \boldsymbol{\Sigma}(\boldsymbol{\theta})}{\partial \boldsymbol{\theta}_i \partial \boldsymbol{\theta}_j}\right\} \\
&+ 2\,\text{tr}\left\{\boldsymbol{\Sigma}(\boldsymbol{\theta})^{-1}\frac{\partial \boldsymbol{\Sigma}(\boldsymbol{\theta})}{\partial \boldsymbol{\theta}_i}\boldsymbol{\Sigma}(\boldsymbol{\theta})^{-1}\frac{\partial \boldsymbol{\Sigma}(\boldsymbol{\theta})}{\partial \boldsymbol{\theta}_j}\boldsymbol{\Sigma}(\boldsymbol{\theta})^{-1}\boldsymbol{S}\right\} \\
&- \text{tr}\left\{\boldsymbol{\Sigma}(\boldsymbol{\theta})^{-1}\frac{\partial^2 \boldsymbol{\Sigma}(\boldsymbol{\theta})}{\partial \boldsymbol{\theta}_i \partial \boldsymbol{\theta}_j}\boldsymbol{\Sigma}(\boldsymbol{\theta})^{-1}\boldsymbol{S}\right\}\Bigg]
\end{aligned}$$

and let the j, kth entry of $\boldsymbol{J}(\boldsymbol{\theta})$ be given by $n^{-1}\partial^2\ell(\boldsymbol{\Sigma}(\boldsymbol{\theta}); \boldsymbol{\Sigma}_0)/\partial\boldsymbol{\theta}_j\partial\boldsymbol{\theta}_j$, which is clearly continuous in $\boldsymbol{\theta}$. Let $\mathcal{N}_0$ be an Euclidean ball that lies fully in the interior of $\boldsymbol{\Theta}$ and which is centred around $\boldsymbol{\theta}_0$. Finally let $\boldsymbol{R}_n = n\boldsymbol{I}_p$. Then

$$\begin{aligned}
\sup_{\boldsymbol{\theta} \in \mathcal{N}_0}\left|n^{-1}\frac{\partial^2 \ell(\boldsymbol{\Sigma}(\boldsymbol{\theta}); \boldsymbol{S})}{\partial \boldsymbol{\theta}_j \partial \boldsymbol{\theta}_k} - \boldsymbol{J}(\boldsymbol{\theta})_{ij}\right| &= \sup_{\boldsymbol{\theta} \in \mathcal{N}_0}\left|\text{tr}\left\{\boldsymbol{B}(\boldsymbol{\theta})\left[\boldsymbol{S} - \boldsymbol{\Sigma}_0\right]\right\}\right| \\
&\leq \sup_{\boldsymbol{\theta} \in \mathcal{N}_0}\|\|\boldsymbol{B}(\boldsymbol{\theta})\|\|_*\|\|\boldsymbol{S} - \boldsymbol{\Sigma}_0\|\|_2 \\
&\leq C\|\|\boldsymbol{S} - \boldsymbol{\Sigma}_0\|\|_2 \\
&= o_p(1),
\end{aligned}$$

where the second line follows by Hoelder's inequality for Schatten-norms and where $\|\|\boldsymbol{A}\|\|_*$ is the sum of all singular values of $\boldsymbol{A}$ and $\|\|\boldsymbol{A}\|\|_2$ is the spectral norm. The third line follows by the Extreme Value Theorem (see, for example, Rudin, 1976, Theorem 4.16) since $\|\|\boldsymbol{B}(\boldsymbol{\theta})\|\|_*$, which is

$$\boldsymbol{B}(\boldsymbol{\theta}) = \text{tr}\left\{\boldsymbol{\Sigma}(\boldsymbol{\theta})^{-1}\frac{\partial \boldsymbol{\Sigma}(\boldsymbol{\theta})}{\partial \boldsymbol{\theta}_i}\boldsymbol{\Sigma}(\boldsymbol{\theta})^{-1}\frac{\partial \boldsymbol{\Sigma}(\boldsymbol{\theta})}{\partial \boldsymbol{\theta}_j}\boldsymbol{\Sigma}(\boldsymbol{\theta})^{-1} - \frac{1}{2}\boldsymbol{\Sigma}(\boldsymbol{\theta})^{-1}\frac{\partial^2 \boldsymbol{\Sigma}(\boldsymbol{\theta})}{\partial \boldsymbol{\theta}_i \partial \boldsymbol{\theta}_j}\boldsymbol{\Sigma}(\boldsymbol{\theta})^{-1}\right\},$$

is continuous in $\boldsymbol{\theta}$ and $\mathcal{N}_0$ is compact. The last line follows since $\boldsymbol{S}$ converges to $\boldsymbol{\Sigma}_0$ in probability as $n \to \infty$ (N1)). Finally, to see that $\boldsymbol{J}(\boldsymbol{\theta}_0)$ is invertible, note that

$$\boldsymbol{J}(\boldsymbol{\theta}_0)_{ij} = \frac{1}{2}\operatorname{tr}\left\{\boldsymbol{\Sigma}_0^{-1}\frac{\partial\boldsymbol{\Sigma}(\boldsymbol{\theta}_0)}{\partial\boldsymbol{\theta}_j}\boldsymbol{\Sigma}_0^{-1}\frac{\partial\boldsymbol{\Sigma}(\boldsymbol{\theta}_0)}{\partial\boldsymbol{\theta}_i}\right\}.$$

Hence, we can write $\boldsymbol{J}(\boldsymbol{\theta}_0)$ as

$$\boldsymbol{J}(\boldsymbol{\theta}_0) = -\frac{1}{2}\mathcal{J}^\top\left(\boldsymbol{\Sigma}_0^{-1}\otimes\boldsymbol{\Sigma}_0^{-1}\right)\mathcal{J},$$

where

$$\mathcal{J} = \left[\operatorname{vec}\left(\frac{\partial\boldsymbol{\Sigma}(\boldsymbol{\theta}_0)}{\partial\boldsymbol{\theta}_1}\right), \quad \operatorname{vec}\left(\frac{\partial\boldsymbol{\Sigma}(\boldsymbol{\theta}_0)}{\partial\boldsymbol{\theta}_2}\right), \quad \cdots, \quad \operatorname{vec}\left(\frac{\partial\boldsymbol{\Sigma}(\boldsymbol{\theta}_0)}{\partial\boldsymbol{\theta}_d}\right).\right]$$

Hence $\boldsymbol{J}(\boldsymbol{\theta}_0)$ is invertible if $\mathcal{J}$ has full column rank. This holds by our identification condition N2).

A15) Let $\mathcal{N}_0$ be as defined above. By assumption N5), $\nabla P^*(\boldsymbol{\theta})$ is continuous and hence, by the Extreme Value Theorem,

$$\begin{aligned}\sup_{\boldsymbol{\theta}\in\mathcal{N}}\left\|n^{-1/2}\nabla P^*(\boldsymbol{\theta})\right\| &= \frac{c_n}{\sqrt{n}}\sup_{\boldsymbol{\theta}\in\mathcal{N}}\|\nabla P(\boldsymbol{\theta})\|\\ &\leq C\frac{c_n}{\sqrt{n}}\\ &= o_p(1),\end{aligned}$$

as required.

$\square$

Lemma 1. *In the setting of Theorem 3 with assumptions N1)-N3), with probability going to one, the ML estimator exists, and there exists a sequence of orthogonal rotation matrices $\boldsymbol{Q}$ such that*

$$\left\|\boldsymbol{\Lambda}(\hat{\boldsymbol{\theta}})\boldsymbol{Q} - \boldsymbol{\Lambda}_0\right\| \xrightarrow{p} 0, \quad \left\|\boldsymbol{\Psi}(\hat{\boldsymbol{\theta}}) - \boldsymbol{\Psi}_0\right\| \xrightarrow{p} 0.$$

Proof. Consider the parameter space $\boldsymbol{\Theta}^* = \operatorname{vec}(\operatorname{vec}(\boldsymbol{\Theta}_1)\otimes\Re_{>0}^p)$, where $\boldsymbol{\Theta}_1$ is the space of all symmetric, positive semidefinite $p\times p$ matrices with rank q. For $\boldsymbol{\theta}\in\boldsymbol{\Theta}^*$ construct the variance-covariance matrix $\boldsymbol{s}(\boldsymbol{\theta})$ by stacking the first p^2 elements of $\boldsymbol{\theta}$ into the symmetric, positive semidefinite matrix $\boldsymbol{M}$ and the remaining p entries of $\boldsymbol{\theta}$ into the diagonal matrix $\boldsymbol{U}$ and let $\boldsymbol{s}(\boldsymbol{\theta}) = \boldsymbol{M}(\boldsymbol{\theta}) + \boldsymbol{U}(\boldsymbol{\theta})$.

Kano (1986, Theorems 3, 4) shows that if $\boldsymbol{\Sigma}_0$ is strongly identifiable in $\boldsymbol{\Theta}^*$ and the criterion function, which we take to be the criterion function of N3) $\boldsymbol{\theta}\in\boldsymbol{\Theta}^*$, i.e.

$$F(\boldsymbol{\Sigma}, \boldsymbol{s}(\boldsymbol{\theta})) = \log\det(\boldsymbol{s}(\boldsymbol{\theta})) + \operatorname{tr}\left((\boldsymbol{s}(\boldsymbol{\theta}))^{-1}\boldsymbol{\Sigma}\right) - p - \log\det(\boldsymbol{\Sigma}),$$

satisfies the condition (A2) (Kano, 1986, Section 3):

(A2) *For any ϵ, there is a scalar $\delta > 0$ such that $\|\boldsymbol{S} - \boldsymbol{\Sigma}_0\| < \delta$ and $F(\boldsymbol{S}, \boldsymbol{s}(\boldsymbol{\theta})) < \delta$ imply that $\|\boldsymbol{s}(\boldsymbol{\theta}) - \boldsymbol{\Sigma}_0\| < \epsilon$,*

then with probability approaching to one, the minimiser of $F(\boldsymbol{S}, \boldsymbol{s}(\boldsymbol{\theta}))$ over $\boldsymbol{\Theta}^*$, exists and is consistent for $\boldsymbol{\Lambda}_0\boldsymbol{\Lambda}_0^\top, \boldsymbol{\Psi}_0$, i.e.

$$\left\|\boldsymbol{M}(\hat{\boldsymbol{\theta}}) - \boldsymbol{\Lambda}_0\boldsymbol{\Lambda}_0^\top\right\| \xrightarrow{p} 0, \quad \left\|\boldsymbol{U}(\hat{\boldsymbol{\theta}}) - \boldsymbol{\Psi}_0\right\| \xrightarrow{p} 0. \tag{S9}$$

Hence, we need to show that

i) Any maximiser in $\boldsymbol{\Theta}^*$ is equivalent to a maximiser in $\boldsymbol{\Theta}$ in that $M(\hat{\boldsymbol{\theta}}) = \boldsymbol{\Lambda}(\hat{\boldsymbol{\theta}})\boldsymbol{\Lambda}(\hat{\boldsymbol{\theta}})$ for some $p\times q$ matrix $\boldsymbol{\Lambda}(\hat{\boldsymbol{\theta}})$ of rank q, that, in conjunction with $\boldsymbol{U}(\hat{\boldsymbol{\theta}})$ is a maximiser of the log-likelihood in $\boldsymbol{\Theta}$

ii) Strong identifiability in $\boldsymbol{\Theta}$ implies strong identifiability in $\boldsymbol{\Theta}^*$,

iii) condition (A2) holds, and

14

iv) (S9) implies that there exists a sequence of orthogonal rotation matrices $\boldsymbol{Q}$ such that $\boldsymbol{\Lambda}(\hat{\boldsymbol{\theta}})\boldsymbol{Q} \to \boldsymbol{\Lambda}_0$ in probability.

We shall prove each property in turn.

i) Note that the parameter spaces $\boldsymbol{\Theta}$ and $\boldsymbol{\Theta}^*$ have the same images under the maps $\boldsymbol{\theta} \mapsto \boldsymbol{\Sigma}(\boldsymbol{\theta}), (\boldsymbol{\theta} \in \boldsymbol{\Theta})$, $\boldsymbol{\theta} \mapsto \boldsymbol{s}(\boldsymbol{\theta}), (\boldsymbol{\theta} \in \boldsymbol{\Theta}^*)$ respectively, as any $\boldsymbol{\Lambda}\boldsymbol{\Lambda}^\top$ is a symmetric, positive semi-definite $p \times p$ matrix, and conversely any such matrix $\boldsymbol{M}$ admits a representation $\boldsymbol{M} = \boldsymbol{\Lambda}\boldsymbol{\Lambda}^\top$, where $\boldsymbol{\Lambda}$ is $p \times q$ with rank q. The property follows by noting that minimising the criterion function F is equivalent to maximising the log-likelihood function.

ii) If $\boldsymbol{\Sigma}_0 = \boldsymbol{\Lambda}_0\boldsymbol{\Lambda}_0^\top + \boldsymbol{\Psi}_0$ is strongly identifiable in $\boldsymbol{\Theta}$, then it is also strongly identifiable in $\boldsymbol{\Theta}^*$ in that for any $\epsilon > 0$, there is a $\delta > 0$ such that for $\boldsymbol{s} = \boldsymbol{M} + \boldsymbol{U}$, $\boldsymbol{M}$ symmetric positive definite $p \times p$ of rank q and $\boldsymbol{U}$ $p \times p$ diagonal positive definite,

$$\||\boldsymbol{s} - \boldsymbol{\Sigma}_0\|| < \delta \implies \||\boldsymbol{M} - \boldsymbol{\Lambda}_0\boldsymbol{\Lambda}_0^\top\|| < \epsilon, \quad \||\boldsymbol{U} - \boldsymbol{\Psi}_0\|| < \epsilon\,.$$

To see this write $\boldsymbol{s} = \boldsymbol{M} + \boldsymbol{U}$ as $\boldsymbol{s} = \boldsymbol{\Lambda}\boldsymbol{\Lambda}^\top + \boldsymbol{U}$. By strong identifiability of $\boldsymbol{\Sigma}_0$ in $\boldsymbol{\Theta}$, we have that

$$\||\boldsymbol{\Lambda}\boldsymbol{Q} - \boldsymbol{\Lambda}_0\|| < \epsilon, \quad \||\boldsymbol{U} - \boldsymbol{\Psi}_0\|| < \epsilon\,.$$

Now let $\boldsymbol{\Delta} = \boldsymbol{\Lambda}\boldsymbol{Q} - \boldsymbol{\Lambda}_0$. Then

$$\begin{aligned}
\||\boldsymbol{\Lambda}\boldsymbol{\Lambda}^\top - \boldsymbol{\Lambda}_0\boldsymbol{\Lambda}_0^\top\|| &= \||(\boldsymbol{\Lambda}_0 - \boldsymbol{\Delta})(\boldsymbol{\Lambda}_0 - \boldsymbol{\Delta})^\top - \boldsymbol{\Lambda}_0\boldsymbol{\Lambda}_0^\top\|| \\
&= \||\boldsymbol{\Lambda}_0\boldsymbol{\Delta}^\top + \boldsymbol{\Delta}\boldsymbol{\Lambda}_0^\top + \boldsymbol{\Delta}\boldsymbol{\Delta}^\top\|| \\
&\leq 2\||\boldsymbol{\Lambda}_0\boldsymbol{\Delta}^\top\|| + \||\boldsymbol{\Delta}\boldsymbol{\Delta}^\top\|| \\
&\leq 2\||\boldsymbol{\Lambda}_0\||\epsilon + \epsilon^2
\end{aligned}\,.$$

Since ϵ can be chosen arbitrarily small, this establishes strong identifiability of $\boldsymbol{\Sigma}_0$ in $\boldsymbol{\Theta}^*$.

iii) Condition (A2) is exactly assumption N3.

iv) We can always find a $p \times q$ matrix $\boldsymbol{\Lambda}(\hat{\boldsymbol{\theta}})$ of rank q, such that $\boldsymbol{M}(\hat{\boldsymbol{\theta}}) = \boldsymbol{\Lambda}(\hat{\boldsymbol{\theta}})\boldsymbol{\Lambda}(\hat{\boldsymbol{\theta}})^\top$. What remains to be shown is that for any such sequence of $\boldsymbol{\Lambda}(\hat{\boldsymbol{\theta}})$, we can find a sequence of orthogonal rotation matrices $\boldsymbol{Q}$ such that $\||\boldsymbol{\Lambda}(\hat{\boldsymbol{\theta}})\boldsymbol{Q} - \boldsymbol{\Lambda}_0\|| \xrightarrow{p} 0$.

From the Orthogonal Procrustes Theorem (see, for example, Golub and Van Loan 2013, Section 6.4.1) we have that for every $\boldsymbol{\Lambda}(\hat{\boldsymbol{\theta}})$, there exists an orthogonal rotation $\boldsymbol{Q}$ such that

$$\left\||\boldsymbol{\Lambda}(\hat{\boldsymbol{\theta}})\boldsymbol{Q} - \boldsymbol{\Lambda}_0\right\||_F^2 = \left\||\boldsymbol{\Lambda}(\hat{\boldsymbol{\theta}})\right\||_F^2 + \|\boldsymbol{\Lambda}_0\|_F^2 - 2\mathrm{tr}\,(\boldsymbol{R})\,, \tag{S10}$$

where $\boldsymbol{R} = \mathrm{diag}(\sigma_1(\boldsymbol{\Lambda}_0^\top\boldsymbol{\Lambda}(\hat{\boldsymbol{\theta}})), \ldots, \sigma_q(\boldsymbol{\Lambda}_0^\top\boldsymbol{\Lambda}(\hat{\boldsymbol{\theta}})))$ is the diagonal matrix of singular values of $\boldsymbol{\Lambda}_0^\top\boldsymbol{\Lambda}(\hat{\boldsymbol{\theta}})$.

Now by (S10), $\left\||\boldsymbol{\Lambda}(\hat{\boldsymbol{\theta}})\right\||_F^2$ converges to $\|\boldsymbol{\Lambda}_0\|_F^2$ in probability. To show that the singular values $\sigma_i(\boldsymbol{\Lambda}_0^\top\boldsymbol{\Lambda}(\hat{\boldsymbol{\theta}}))$ converge to $\sigma_i(\boldsymbol{\Lambda}_0^\top\boldsymbol{\Lambda}_0)$, note that these singular values are the square roots of the eigenvalues of $\boldsymbol{T}_n = \boldsymbol{\Lambda}_0^\top\boldsymbol{\Lambda}(\hat{\boldsymbol{\theta}})\boldsymbol{\Lambda}(\hat{\boldsymbol{\theta}})^\top\boldsymbol{\Lambda}_0$. Let $\boldsymbol{T} = \boldsymbol{\Lambda}_0^\top\boldsymbol{\Lambda}_0\boldsymbol{\Lambda}_0^\top\boldsymbol{\Lambda}_0$. Then

$$\begin{aligned}
\||\boldsymbol{T}_n - \boldsymbol{T}\||_2 &= \left\||\boldsymbol{\Lambda}_0(\boldsymbol{\Lambda}(\hat{\boldsymbol{\theta}})\boldsymbol{\Lambda}(\hat{\boldsymbol{\theta}})^\top - \boldsymbol{\Lambda}_0\boldsymbol{\Lambda}_0^\top)\boldsymbol{\Lambda}_0^\top\right\||_2 \\
&\leq \||\boldsymbol{\Lambda}_0\||_2\left\||\boldsymbol{\Lambda}(\hat{\boldsymbol{\theta}})\boldsymbol{\Lambda}(\hat{\boldsymbol{\theta}})^\top - \boldsymbol{\Lambda}_0\boldsymbol{\Lambda}_0^\top\right\||_2 \\
&\xrightarrow{p} 0
\end{aligned}\,.$$

By Weyl's inequality (see, for example, Golub and Van Loan 2013, Corollary 8.16),

$$\left|\lambda_i(\boldsymbol{T}_n) - \lambda_i(\boldsymbol{T})\right| \leq \||\boldsymbol{T}_n - \boldsymbol{T}\||_2 \xrightarrow{p} 0, \quad (i = 1, \ldots, q)\,.$$

Thus the singular values $\sigma_i(\boldsymbol{\Lambda}_0^\top\boldsymbol{\Lambda}(\hat{\boldsymbol{\theta}}))$, which are the square roots of $\lambda_i(\boldsymbol{T}_n)$, converge to $\sigma_i(\boldsymbol{\Lambda}_0^\top\boldsymbol{\Lambda}_0)$, the square roots of $\lambda_i(\boldsymbol{T})$. Therefore

$$\mathrm{tr}\,(\boldsymbol{R}) \xrightarrow{p} \sum_{i=1}^{q} \sigma_i(\boldsymbol{\Lambda}_0^\top\boldsymbol{\Lambda}_0) = \|\boldsymbol{\Lambda}_0\|_F^2\,,$$

15

and thus by (S10) indeed

$$\left\|\!\left\|\mathbf{\Lambda}(\hat{\boldsymbol{\theta}})\boldsymbol{Q} - \mathbf{\Lambda}_0\right\|\!\right\|_F^2 \xrightarrow{p} 0\,.$$

$\square$
